1 Introduction

This document specifies the Office Drawing Binary File Format Structure, which enables the use of graphical elements in certain applications.

Sections 1.7 and 2 of this specification are normative. All other sections and examples in this specification are informative.

1.1 Glossary

This document uses the following terms:

absolute space: An area of a drawing that occupies an entire document or page. The value for absolute space is typically expressed in **English Metric Units (EMUs)**, but it can be defined by the host application.

Active Server Pages (ASP): A server-side scripting engine that was developed by Microsoft and is designed to dynamically generate a webpage.

adjust handle: A user interface control that is located on an object frame and is used to increase or decrease the size of that object.

anchor: A set of qualifiers and quantifiers that specifies the location of an element or object within a document. These values are typically relative to another element or known location in the document, such as the edge of a page or margin.

atom: A unit of information that cannot be divided into smaller parts, and is accepted or rejected in its entirety. See also Atom Publishing Protocol (AtomPub).

background shape: A graphical drawing object that is covered or obstructed by other shapes in the foreground.

binary large image or picture (BLIP): A binary data structure that stores information about a metafile image or bitmap picture.

bounding rectangle: A frame that encompasses an object. A bounding rectangle is not rotated and, therefore, always aligns along the x and y axes.

Hypertext Markup Language (HTML): An application of the Standard Generalized Markup Language (SGML) that uses tags to mark elements in a document, as described in [\[HTML\]](#).

1.3 Structure Overview (Synopsis)

Certain applications use the Office Drawing Binary File Format Structure to represent **drawing** elements and their associated formatting. Typically, these elements are represented as **shapes** that are contained within drawings or **diagrams**, but the elements can also include form controls and tables. This file format is also known as OfficeArt.

The host application stores the OfficeArt data as a series of records, many of which contain additional records. The host application, which determines where to store the OfficeArt data, can also define and store additional records—to provide the details that are needed to position the drawing elements in the host document or to render any associated text. To allow the OfficeArt records to be parsed without detailed knowledge of each record type, each record has a common header that contains the record type and additional data.

OfficeArt uses an object container hierarchy, which is illustrated by the following figure.

Figure 1: Object container hierarchy

At the root of the hierarchy is a **drawing group** object. Each client document has one drawing group. A drawing group contains drawings. A drawing contains shapes, which are the objects that populate a page. Adjacent to the drawings in a drawing group is a collection that contains the **binary large images or pictures (BLIPs)** that are used by the drawings. OfficeArt stores pictures in a separate collection so that they can be incrementally loaded and saved and so that the duplication of picture data will be reduced.

Associated with each shape is a piece of client data that stores the **anchor**, text, and **Object Linking and Embedding (OLE)** data of the shape as well as host-specific properties. The host application specifies the format of this structure. A separate structure, called a property table, stores the properties of the shape. A property table consists of a list of identifier-value pairs, where each identifier represents a property.

Each drawing group has a shape property table that stores the defaults for new shapes.

Each drawing has a collection of **rules** that govern the shapes in the drawing.

Note that drawings are not saved inside drawing groups but in separate, top-level containers. This scheme enables host applications to save drawing group information with per-document information and to save drawing information with per-sheet, per-**slide**, or per-page information.

The remainder of this section describes the Office Drawing Binary File Format Structure in more detail.

1.3.1 Records

The OfficeArt file stream consists of a series of records that share a common header structure. Records can be categorized into two groups: **atoms** and containers.

An atom is a record that contains information about an OfficeArt object and is kept inside a container.

A container is a record that contains atoms and other containers in a logical and organized way.

Each record, whether atom or container, has a common header. A container consists of just the common header, whereas an atom consists of the common header followed by record-specific data.

A group of records that each end in the word *FileBlock* indicates an abstract form of concrete records that might be in a collection. The containing record stores an array of *FileBlock* records that each represent an instance of a different record type, as determined by a field within the record header of the *FileBlock* record.

1.3.2 Record Headers

All records share a common header that describes the record data. This header contains the record type, the record length, and if the record is an atom, a version identifier. Although every record type has an instance property, not every record type uses this field. When used, the instance property specifies either the number of objects in the container record or a specific identifier that is used by the record.

Because the header specifies the record length, it is possible to parse an OfficeArt record stream without knowledge of the actual contents of each record. It is expected that parsers of the Office Drawing Binary File Format Structure will skip over record types that are unknown to the reader. In addition, parsers need to expect that records can come in any order in a container. On the other hand, parsers can expect that the container hierarchy will not change. For example, it is unnecessary to consider a **shape** record that contains a **drawing** record.

When the data is written to a client file, the host application stores client-specific records in the OfficeArt stream to preserve the client features and behaviors. For more information, see section [1.4](#).

1.3.3 Containers

A container consists of a record header, which is followed by the contained records. A container needs to precede all atoms because the container specifies how the contained atoms are to be applied to the **drawing** data. For example, a **shape** container and a **drawing group** container each contain a collection of properties. The container designates that the properties are either individual shape properties or document default properties.

1.3.4 Properties

Because the Office Drawing Binary File Format Structure contains **drawing** data, it is heavily populated with properties that are specific to **shapes**. These shape properties are contained in a set of sparsely populated arrays. Each array contains a specific block of properties and contains only those properties for which the value differs from the default. If a property is specified to be ignored or is omitted from the file, it is assumed to have the default value.

If any property appears in a property block more than once, the last occurrence is assumed to be the correct property, and the value in the last occurrence overrides any previously set value.

1.3.5 Bit Format

Records are tightly packed without alignment. OfficeArt data is stored in **little-endian** format.

1.3.6 Extended Colors

Each property that is related to color has two associated extended-color properties, which can be used to define the main color more precisely. If neither extended-color property is set, the main color property contains the full color definition. Otherwise, the first extended-color property specifies the base color, and the second extended-color property specifies a tint or shade modification that is applied to the first extended-color property. In this case, the main color property contains the

flattened **red-green-blue (RGB)** color that is computed by applying specified tint or shade modification to the specified base color. If the values of the main color property and the extended-color properties are inconsistent, the value of the main color property can be used and those of the extended-color properties discarded. For more information, see section [2.2.2](#).

1.4 Relationship to Protocols and Other Structures

The Office Drawing Binary File Format Structure is dependent on the structures that are defined in the following references:

- [\[MS-DOC\]](#)
- [\[MS-XLS\]](#)
- [\[MS-PPT\]](#)
- [\[MS-OGGRAPH\]](#)

These structures determine how the OfficeArt data is saved to disk and where that data will reside. Additionally, images are stored within the file in standard raster formats. The **OfficeArtBStoreContainerFileBlock** record, which is defined in section [2.2.22](#), specifies which image types are supported within the **BLIP** store.

The host application defines a certain group of records within the OfficeArt stream as client records. These records hold information that the host application needs to position the **diagram** in the host document or to contain the host text.

The host application supplies OfficeArt text to provide the same functionality as the application's native text. Some host applications also apply rules to the **shapes** or diagrams to assist with positioning those shapes or diagrams or to store additional data for other host-specific needs.

For more information, see [\[MS-DOC\]](#), [\[MS-XLS\]](#), [\[MS-PPT\]](#), and [\[MS-OGGRAPH\]](#).

1.5 Applicability Statement

This document specifies a persistence format for **drawings**. These drawings typically contain geometric primitives, also known as **shapes**, that might contain formatting elements such as fills, line styles, pictures, and three-dimensional (3-D) transformations. These shapes also support text as specified by the host application.

This persistence format provides interoperability with applications that create or read documents conforming to this structure.

1.6 Versioning and Localization

This document covers versioning issues in the following areas:

Structure versions: All of the custom OfficeArt types, as defined in section [2.1](#), and OfficeArt record types, as defined in section [2.2](#), are supported by all versions of the OfficeArt file format, but this is not true for all of the properties. For more information, see section [2.3](#).

Localization: The OfficeArt file format does not use localized user text strings. This file format does use properties to represent text orientation and flow, as needed. For more information, see sections [2.3.21.9](#), [2.3.21.10](#), and [2.3.21.12](#). All the units of measure that are described in this document are either application defined, explicitly specified, or consistent across all locales. The OfficeArt file format does not define any time formats, calendar formats, or monetary units.

1.7 Vendor-Extensible Fields

A vendor or third party can add data to the OfficeArt file format by defining a new record that has a record header for which the record type is outside the range 0xF000 through 0xFFFF. When a record type is encountered outside this range, the record MAY be skipped. For the record to be skipped, the record length field also needs to represent the size of the record so that the reader can determine how far ahead to jump to continue parsing the file. Any vendor-defined record MUST have a valid record header, as specified in the **OfficeArtRecordHeader** structure, as defined in section [2.2.1](#), for the record to be skipped as an unknown record type. Similarly, if a vendor or third party needs to add additional properties, a new record type needs to be defined to contain these properties. The existing OPT tables are as follows:

- **OfficeArtFOPT**, as defined in section [2.2.9](#).
- **OfficeArtSecondaryFOPT**, as defined in section [2.2.10](#).
- **OfficeArtTertiaryFOPT**, as defined in section [2.2.11](#).

Avoid adding new properties to one of these existing OPT tables with a previously unused value in the **opid** field. These values might be claimed by a later version of OfficeArt and would then cause collisions with the vendor data. If a property has an unrecognized **opid.opid** field, a vendor can ignore the property.

A vendor cannot acquire a record number that is guaranteed to be uniquely its own. Therefore, vendor-defined records risk causing conflicts with records that are defined by other vendors or third parties.

A vendor can choose to infer the text orientation and flow either from the character context (by inspecting the characters and determining the correct orientation and flow from the **Unicode** character set) or from the system locale settings.

If neither extended-color property is set, the main **color** property contains the full color definition. Otherwise, the **colorExt** property specifies the base color, and the **colorExtMod** property specifies a tint or shade modification that is applied to the **colorExt** property. In this case, the main **color** property contains the flattened **RGB** color that is computed by applying the specified tint or shade modification to the specified base color.

A - unused1 (1 bit): A bit that is undefined and MUST be ignored.

B - unused2 (1 bit): A bit that is undefined and MUST be ignored.

C - unused3 (1 bit): A bit that is undefined and MUST be ignored.

D - fSysIndex (1 bit): A bit that specifies whether the system **color scheme** will be used to determine the color. A value of 0x1 specifies that **green** and **red** will be treated as an unsigned 16-bit index into the system color table. Values less than 0x00F0 map directly to system colors. For more information, see [\[MSDN-GetSysColor\]](#).

The following table specifies values that have special meaning.

Value	Meaning
0x00F0	Use the fill color of the shape .
0x00F1	If the shape contains a line, use the line color of the shape. Otherwise, use the fill color.
0x00F2	Use the line color of the shape.
0x00F3	Use the shadow color of the shape.
0x00F4	Use the current, or last-used, color.
0x00F5	Use the fill background color of the shape.
0x00F6	Use the line background color of the shape.
0x00F7	If the shape contains a fill, use the fill color of the shape. Otherwise, use the line color.

The following table specifies values that indicate special procedural properties that are used to modify the color components of another color. These values are combined with those in the preceding table or with a user-specified color. The first six values are mutually exclusive.

Value	Meaning
0x0100	Darken the color by the value that is specified in the blue field. A blue

Value	Meaning
	value of 0xFF specifies that the color is to be left unchanged, whereas a blue value of 0x00 specifies that the color is to be completely darkened.
0x0200	Lighten the color by the value that is specified in the blue field. A blue value of 0xFF specifies that the color is to be left unchanged, whereas a blue value of 0x00 specifies that the color is to be completely lightened.
0x0300	Add a gray level RGB value. The blue field contains the gray level to add: NewColor = SourceColor + gray
0x0400	Subtract a gray level RGB value. The blue field contains the gray level to subtract: NewColor = SourceColor - gray
0x0500	Reverse-subtract a gray level RGB value. The blue field contains the gray level from which to subtract: NewColor = gray - SourceColor
0x0600	If the color component being modified is less than the parameter contained in the blue field, set it to the minimum intensity. If the color component being modified is greater than or equal to the parameter, set it to the maximum intensity.
0x2000	After making other modifications, invert the color.
0x4000	After making other modifications, invert the color by toggling just the high bit of each color channel.
0x8000	Before making other modifications, convert the color to grayscale.

E - fSchemeIndex (1 bit): A bit that specifies whether the current application-defined color scheme will be used to determine the color. A value of 0x1 specifies that **red** will be treated as an index into the current color scheme table. If this value is 0x1, **green** and **blue** MUST be 0x00.

F - fSystemRGB (1 bit): A bit that specifies whether the color is a standard RGB color. The following table specifies the meaning of each value for this field.

Value	Meaning
0x0	The RGB color MAY use halftone dithering to display.
0x1	The color MUST be a solid color.

G - fPaletteRGB (1 bit): A bit that specifies whether the current palette will be used to determine the color. A value of 0x1 specifies that **red**, **green**, and **blue** contain an RGB value that will be matched in the current color palette. This color MUST be solid.

H - fPaletteIndex (1 bit): A bit that specifies whether the current palette will be used to determine the color. A value of 0x1 specifies that **green** and **red** will be treated as an unsigned 16-bit index into the current color palette. This color MAY <1> be dithered. If this value is 0x1, **blue** MUST be 0x00.

blue (1 byte): An unsigned integer that specifies the intensity of the blue color channel. A value of 0x00 has the minimum blue intensity. A value of 0xFF has the maximum blue intensity.

green (1 byte): An unsigned integer that specifies the intensity of the green color channel. A value of 0x00 has the minimum green intensity. A value of 0xFF has the maximum green intensity.

red (1 byte): An unsigned integer that specifies the intensity of the red color channel. A value of 0x00 has the minimum red intensity. A value of 0xFF has the maximum red intensity.

opid (14 bits): An unsigned integer that specifies the identifier of the property in this entry.

A - fBid (1 bit): A bit that specifies whether the value in the **op** field is a **BLIP** identifier. If this value equals 0x1, the value in the **op** field specifies the BLIP identifier in the **OfficeArtBStoreContainer** record, as defined in section [2.2.20](#). If **fComplex** equals 0x1, this bit MUST be ignored.

B - fComplex (1 bit): A bit that specifies whether this property is a complex property. If this value equals 0x1, the **op** field specifies the size of the data for this property, rather than the property data itself.

2.2.61 MSOSHADECOLOR

The **MSOSHADECOLOR** record specifies an intermediate color in the gradient fill and its relative position along the **gradient vector**.

0	1	2	3	4	5	6	7	8	9	10	1	2	3	4	5	6	7	8	9	20	1	2	3	4	5	6	7	8	9	30	1
color																															
position																															

color (4 bytes): An **OfficeArtCOLORREF** record, as defined in section [2.2.2](#), that specifies what color to use in this point. The color in the specified position is pure. Before and after this position the color can be in transition (or pure, depending on whether this is the last position or not).

The value MUST be from 0.0 through 1.0, inclusive. A value of 0.0 specifies the start of the gradient. A value of 1.0 specifies the end of the gradient.

2.3 Properties

Three property blocks— **OfficeArtFOPT** record, as defined in section [2.2.9](#), **OfficeArtSecondaryFOPT** record, as defined in section [2.2.10](#), and **OfficeArtTertiaryFOPT** record, as defined in section [2.2.11](#), are associated with each **shape** instance. The **OfficeArtSpContainer** record, as defined in section [2.2.14](#), contains each of these property blocks. The **OfficeArtFOPT** and **OfficeArtTertiaryFOPT** property blocks, which are saved with the **drawing group** **OfficeArtDggContainer**, as defined in section [2.2.12](#), establish new defaults for every shape in the file. For example, if the fill color for the drawing group is set to red, any shape in any **diagram** that persists in the file without its own fill color will use red. If no fill color exists in either the document properties or the shape, the default fill color will be used.

If the **fComplex** flag of a property equals 0x1, that property has more data than will fit in the four bytes associated with the simple property types. In this case, the **op** field contains the number of bytes that follow the **OfficeArtRGFOPT** records, as defined in section [2.3.1](#), and that contain the property data.

The structures that are specified in this section are supported at the file level by the applications, but not every application writes every property to the binary file. An application that does not fully support a property can load and save that property unchanged, which is the case for any property introduced in a later version of an application that is opened by an earlier version of the same application. Scenarios also exist in which a later version of an application supports a deprecated property or value by converting it to another property or value and then removing the deprecated one.

pInscribe_complex (variable)																															
...																															

pInscribe_complex (variable): An **IMsoArray** record, as defined in section [2.2.51](#), of **RECT** records, as defined in section [2.2.56](#), that specify the rectangle within this **shape** in which text is inscribed. The coordinates in the **RECT** records are specified in the **geometry space**, unless a coordinate exists in the range from 0x80000000 through 0x8000007F. In that case, the value is not used directly. Instead, the final value is calculated by subtracting 0x80000000 from the original value, and then using that value as the zero-based index into the **pGuides_complex** array, as defined in section [2.3.6.27](#), to specify the value that is used.

The algorithm for calculating the inscribed rectangle varies based on the number of rectangles that are provided and on whether the text exists in a horizontal or a vertical layout. The text is laid out vertically if the **txflTextFlow** property of this shape equals **msotxfITtoBA**, **msotxfIBtoT**, **msotxfITtoBN**, or **msotxfIVertN**. Otherwise, the text is laid out horizontally. The number of rectangles that are provided MUST be zero, one, two, three, or six. The following table describes the meaning of each of these numbers of rectangles.

Number of rectangles	Meaning
Zero	The text is inscribed in the rectangle within the shape.
One	The text is inscribed in the single rectangle that is provided.
Two	If the text exists in a horizontal layout, it is inscribed in the first rectangle that is provided. If the text exists in a vertical layout, it is inscribed in the second rectangle that is provided.
Three	The three rectangles specify the minimum, middle, and maximum rectangles to use for both vertical and horizontal layouts. If the pAdjustHandles_complex property, as defined in section 2.3.6.25 , is either not specified or empty, the minimum rectangle is used. Otherwise, the adjustValue property, as defined in section 2.3.6.10 , and the first ADJH record, as defined in section 2.2.57 , in the pAdjustHandles_complex property are used to determine how to interpolate among the three rectangles. If the apX value of the first ADJH record is controlling the adjustValue property because it equals 0x00000100, the adjustValue property is compared with xMin and xMax . Otherwise, the adjustValue property is compared with yMin and yMax . If the value of the adjustValue property is less than the midway point between these values, the inscribed rectangle is calculated by a linear interpolation between the minimum and middle rectangles. If the value of the adjustValue property is greater than the midway point between these values, the inscribed rectangle is calculated by a linear interpolation between the middle and maximum rectangles.
Six	The first three rectangles specify the minimum, middle, and maximum rectangles to use if the text exists in a horizontal layout. The last three rectangles specify the minimum, middle, and maximum rectangles to use if the text exists in a vertical layout. The same algorithm as the one for the case of three rectangles is used.

	 <p>The <i>A</i> spacing is the width to add to the current position before placing the character. The <i>B</i> spacing is the width of the character itself. The <i>C</i> spacing is the white space to the right of the character. The total advance width is determined by calculating the sum of $A+B+C$. Because characters can overhang or underhang the character cell, either or both of the <i>A</i> and <i>C</i> increments can be negative numbers.</p>

3 Structure Examples

This section contains examples that illustrate different features of the Office Drawing Binary File Format Structure.

The example structures are derived from sample files<124>. The example structures will be similar for other applications<125>, but records and fields that are defined by the client application might vary slightly.

3.1 Diagram

This section provides an example of the record hierarchy within a **drawing** container that specifies the structure of a **diagram**. This section outlines some of the records that define the structure and properties specific to the following **drawing objects**<126>:

- Basic **shapes**, including:
 - Shape fill and color
 - Shape outline
 - Shape position
 - Shape grouping
- Text
- Diagram type, layout, and protection
- **Connector** lines

The diagram image that is shown in the following figure represents a basic organizational-chart diagram, which consists of a top-level shape, an assistant shape, coworker shapes, and a subordinate shape. Each shape in the diagram contains text, a fill color, and a shape outline. All of the shapes are connected by lines that are called connectors.

Figure 10: Basic organizational chart

The remainder of this section shows the record hierarchy that is used to define a diagram and the shapes that are used to construct a diagram. For a detailed specification of each record that is mentioned, see Structures, as defined in section 2.

3.1.1 DrawingContainer

All the records that are used to construct the multiple parts of a **diagram** are stored in the **drawing** container. The drawing container is defined by the host application and might be named differently in the file format of the host application.

The following table shows the child-record hierarchy of the **DrawingContainer** record ([MS-PPT] section 2.5.13) named **drawing**. This example focuses on the four top-level containers, which are labeled **1**, **2**, **3**, and **4** within the **OfficeArtDgContainer** record, as defined in section 2.2.13.

OfficeArtDg.groupShape: An **OfficeArtSpgrContainer** record, as defined in section 2.2.16, that contains groups of shapes. This group container contains a variable number of shape containers and other group containers. The group itself is a shape.

OfficeArtDg.shape: An **OfficeArtSpContainer** record, as defined in section 2.2.14, that acts as a container for shapes.

OfficeArtDg.solvers: An **OfficeArtSolverContainer** record, as defined in section 2.2.18, that acts as a container for **rules** that are applicable to shapes.

The containers that are labeled **1**, **2**, **3**, and **4** are described in more detail in the following four subsections.

Figure 12: Child-Record Hierarchy of OfficeArtFDG Container 1

The records that are contained within **OfficeArtFDG** container **1** are specified as follows:

rh: An **OfficeArtRecordHeader** structure, as defined in section 2.2.1, that describes the record data. This 8-byte header contains the record type, the record length, and if it is an **atom** type, a version identifier.

rh.recVer: The record version, which is 0x0 if the record is an atom or 0xF if the record is a container.

rh.recInstance: The record instance (0x002), which is useful for differentiating atoms when more than one atom of the same type exists in a particular container.

rh.recType: The type (0xF008) of the record. OfficeArt uses values from 0xF000 to 0xFFFF. Client applications can define their own records by using other ranges.

rh.recLen: The length (0x00000008), in bytes, of the record. If the record is an atom, this value specifies the length of the atom excluding the header. If the record is a container, this value specifies the sum of the lengths of the contained atoms plus the length of the record header for each atom.

csp: The number (0x0000000E) of **shapes** in this **drawing**.

spidCur: The shape identifier (0x00000818) of the last shape in this drawing.

3.2.3 Shape Text Properties

The text in a **shape** is host-dependent, and not all the text properties are supported by each host application.

The text-related fields and records in this section are defined by the host application. For more information, see [\[MS-PPT\]](#) section 2.9.76.

The following table shows the **OfficeArtClientTextbox** record.

Figure 55: OfficeArtClientTextbox Shape Text Properties

The records contained within the **OfficeArtClientTextbox** container that have not been explained in previous structure examples are specified as follows:

clientTextbox: A container that specifies text-related data for a shape.

rgChildRec: An array of **TextClientDataSubContainerOrAtom** records that specifies text-related data.

rgChildRec.rec: A variable-type record for which the type and meaning are dictated by the value of **rh.recType**.

rgChildRec.rec.case_of_RT_TextHeaderAtom: An **atom** that specifies the type of a text body. The presence of this atom indicates a text body that has properties specified by subsequent atoms and containers.

rgChildRec.rec.case_of_RT_TextHeaderAtom.textType: A value that specifies the text type. The value 0x00000004 specifies that the text type is the **TextTypeEnum** enumeration value **Tx_TYPE_OTHER**, which means any other text.

rgChildRec.rec.case_of_RT_TextBytesAtom: An atom that specifies Unicode characters.

rgChildRec.rec.case_of_RT_TextBytesAtom.textBytes: An array of bytes that specifies the characters ("Shape with text") of the corresponding text within the shape.

rgChildRec.rec.case_of_RT_StyleTextPropAtom: An atom that specifies both character-level and paragraph-level formatting.

Preliminary

4 Security Considerations

This file format allows **HTML** code and associated script to be inserted into a **shape**. When the shape is exported to an HTML format, it is possible that the associated script could be executed. Whether this happens is dependent on the nature of the script and how the HTML document is opened.

The [Signature Line](#) can contain personally identifiable information, such as the user's name or e-mail address. This information is not mandatory and can be replaced by defaults or omitted entirely. For privacy reasons, applications ought to provide users with a way to remove this information from files. Personally identifiable information in this file format is not backed by any kind of authentication system. For example, the signer's name does not need to be tied to the author's logon credentials nor to any other form of identity verification. Therefore, it is not advisable for applications to make security decisions based on this information.

5 Appendix A: Product Behavior

The information in this specification is applicable to the following Microsoft products or supplemental software. References to product versions include updates to those products.

- Microsoft Office 97
- Microsoft Office 2000
- Microsoft Office XP

Exceptions, if any, are noted in this section. If an update version, service pack or Knowledge Base (KB) number appears with a product name, the behavior changed in that update. The new behavior also applies to subsequent updates unless otherwise specified. If a product edition appears with the product version, behavior is different in that product edition.

Unless otherwise specified, any statement of optional behavior in this specification that is prescribed using the terms "SHOULD" or "SHOULD NOT" implies product behavior in accordance with the SHOULD or SHOULD NOT prescription. Unless otherwise specified, the term "MAY" implies that the product does not follow the prescription.
