## 1.3 Protocol Overview

The Remote Operations (ROP) List and Encoding protocol specifies the details of each remote operation (ROP).

**ROP buffers** are used by the client to send operation requests to the server and by the server to send responses back to the client. These requests specify operations that access and modify mailbox data on a server, such as the following:

- Log on to mailboxes or public folders on a server
- Retrieve the list of folders and messages on a mailbox
- Move and copy messages or folders from one location to another
- Sort and filter views of messages or folders
- Submit new messages for delivery to other mailboxes or servers
- Retrieve a list of changes made to messages and folders
- Register for notifications when contents of a mailbox have changed

In a typical scenario, a client packages one or more **ROP requests** into a ROP buffer and makes a function call on the **EMSMDB** interface, as specified in [MS-OXCRPC], passing the buffer. The server then parses the ROP requests from the buffer. Each request is executed and a **ROP response** is added to the output ROP buffer. Once the server is done processing the input ROP buffer, the function call returns the responses to the client.

### 1.3.1 Server Objects

A **Server Object** refers to an object created during execution of specific ROPs. Once created, a Server Object can then be used as a parameter for other ROPs until it is released. A Server Object is typically a view of data on the server, such as a **folder** or a message object, but it could also be an object used to control synchronization or change notifications.

A Server Object is identified in a ROP buffer by a **Server Object Handle**, a 32-bit handle value. This handle is assigned by the server when the Server Object is created. A client uses a Server Object Handle to specify a Server Object to be used as input for a ROP request.

### 1.3.2 Format of ROP Buffers

A ROP buffer contains a list of ROP requests or responses followed by a **Server Object Handle Table**. Each request contains input values to use for an operation. Each response contains output produced during the execution of previous requests. The Server Object Handle Table contains Server Object Handles that are used as input or output for ROPs.

With few exceptions, a ROP request or response does not directly specify Server Object Handles, but instead contains an index into the Server Object Handle Table. When the index is used for an input parameter, it specifies the location of the Server Object Handle identifying the input Server Object. When the index is used for an output parameter, it specifies the entry in the Server Object Handle Table where the handle for the created Server Object will be stored if the operation is successful. If the operation is unsuccessful, the content of the entry in the Server Object Handle Table is undefined.

The usage of an index allows a client to create a ROP buffer consisting of ROP requests that reference as an input parameter a Server Object created earlier during processing of the buffer. In this way, fewer round-trip calls between the client and server are necessary.

## 1.4 Relationship to Other Protocols

The Remote Operations (ROP) List and Encoding protocol is dependent upon the Wire Format protocol, as specified in [MS-OXCRPC]. The ROP buffers are sent and received as parameters of the **EcDoRpcExt2** function on the **EMSMDB** interface. In addition, information provided during the **EcDoConnectEx** calls on the same interface is used later when executing ROP requests.

There are a number of protocols that are built on the Remote Operations (ROP) List and Encoding protocol. Some examples include the Bulk Data Transfer protocol, specified in [MS-OXCFCICS], and the Property and Stream Object protocol, specified in [MS-OXCPRPT].

There are several protocols which can be considered alternatives to the Remote Operations (ROP) List and Encoding protocol. These alternatives include IMAP4 and Distributed

Authoring and Versioning (DAV). For details about IMAP4, see [MS-OXIMAP4]. For details about DAV, see [MS-XWDVSEC].

### ***1.5 Prerequisites/Preconditions***

The Remote Operations (ROP) List and Encoding protocol assumes that a connection was already made using the **EMSMDB** interface, as specified in [MS-OXCRPC]. The connection process authenticates and exchanges version information between the server and client.

Successful communication between the client and server requires that the client is already configured with information about the mailbox and server. Several ROPs make use of a distinguished name (DN) as an input field to specify a mailbox or a server.

### ***1.6 Applicability Statement***

This protocol is used to view and modify mailbox and public folder data. It provides broad low-level access to the contents that are on the server.

### ***1.7 Versioning and Capability Negotiation***

None.

### ***1.8 Vendor-Extensible Fields***

None.

### ***1.9 Standards Assignments***

None.

## **2 Messages**

Unless otherwise specified, buffers and fields in this section are depicted in little-endian byte order.

### ***2.1 Transport***

The ROP request and response buffers specified in the following sections are sent and received by using the **EcDoRpcExt2** RPC functions, as specified in [MS-OXCRPC].

### ***2.2 Message Syntax***

Each ROP request and response buffer consists of the following structure.

**RopSize (2 bytes):** Unsigned 16-bit integer. This value specifies the size of this field and the **Rops** field.

**Rops (variable):** List of ROP buffers. The number of bytes in this field MUST be 2 bytes less than the value specified in the **RopSize** field. The formats of the ROP buffers are specified in subsequent sections.

**ServerObjectHandleTable (variable):** Array of 32-bit identifiers. The length of this field is the length of the remaining data in the buffer after the **Rops** field. These identifiers specify the Server Object Handles that are referenced in the **Rops** field.

### 2.2.1 The Table of RopIds

Each ROP is identified by a one-byte value, which is contained in the **RopId** field of ROP request and response buffers. The ROPs that a client is allowed to use are included in the following table. A ROP that is specified as "Reserved" is not used in the communication between the client and server. Therefore, the client MUST NOT use the reserved ROPs.

The server SHOULD <1> return an error for the RPC call when it encounters a **RopId** value that is associated with a reserved ROP.

## 2.2.2 Logon ROPs

### 2.2.2.1 RopLogon

This remote operation logs on to a mailbox or public folder. More detailed information about this operation can be found in [MS-OXCSTOR].

#### 2.2.2.1.1 Request Buffer

**RopId (1 byte):** Unsigned 8-bit integer. This value specifies the type of remote operation. This field **MUST** be set to 0xFE.

**LogonId (1 byte):** Unsigned 8-bit integer. This value specifies the ID that the client wants associated with the created logon. Any value is allowed and the client does not have to use values in a certain numeric order. If the client specifies an active logon ID, the current logon is released and replaced with the new one.

**OutputHandleIndex (1 byte):** Unsigned 8-bit integer. This index specifies the location in the Server Object Handle Table where the handle for the output Server Object will be stored. More information about Server Objects can be found in section 3.

**LogonFlags (1 byte):** 8-bit flags structure. The possible values are specified in [MS-OXCSTOR]. This structure contains flags that control the behavior of the logon.

**OpenFlags (4 byte):** 32-bit flags structure. The possible values are specified in [MS-OXCSTOR]. This structure contains more flags that control the behavior of the logon.

**StoreState (4 bytes):** 32-bit flags structure. The possible values are specified in [MS-OXCSTOR]. This structure specifies ongoing action on the mailbox or public folder.

**EssdnSize (2 bytes):** Unsigned 16-bit integer. This value specifies the size of the **Essdn** field.

**Essdn (variable):** Null terminated ASCII string. This string **MUST** contain the same number of characters (including the null) as specified in the **EssdnSize** field. This string specifies which mailbox to log on to.

This remote operation releases all resources associated with a Server object. For more details about the dependencies of Server objects, see section 3.1.5.2.

##### 2.2.14.3.1 Request Buffer

**RopId (1 byte):** Unsigned 8-bit integer. This value specifies the type of remote operation. This field MUST be set to 0x01.

**LogonId (1 byte):** Unsigned 8-bit integer. This value specifies the logon associated with this operation.

**InputHandleIndex (1 byte):** Unsigned 8-bit integer. This index specifies the location in the Server Object Handle Table where the handle for the input Server Object is stored. More information about Server Objects can be found in section 3.

## 3 Protocol Details

### 3.1 Client Details

#### 3.1.1 Abstract Data Model

This section describes a conceptual model of possible data organization that an implementation maintains to participate in this protocol. The described organization is provided to facilitate the explanation of how the protocol behaves. This document does not mandate that implementations adhere to this model as long as their external behavior is consistent with that described in this document.

**Logon Collection:** A collection of LogonIds in use.

**Server Object Handle Collection:** A collection of valid Server Object Handles received from the server but not yet released.

#### 3.1.2 Timers

None.

#### 3.1.3 Initialization

None.

#### 3.1.4 Higher-Layer Triggered Events

The client creates ROP buffers consisting of ROP requests for operations to be performed on the server. This input buffer is sent to the server and an output ROP buffer is received back from the server.

##### 3.1.4.1 Creating an Input ROP Buffer

An input ROP buffer is constructed by the client and sent to the server. The client packages its ROP requests together in the intended execution order and creates an associated Server Object Handle Table.

When assembling an input ROP buffer, the client **MUST** use a Server Object Handle Table large enough to include an entry for the largest index used by ROP requests in the buffer. Each entry in the table that is only referenced as input indexes for ROPs **MUST** be filled in with the handle of the Server Object that is intended to be the input of the operation. Each entry that is only referenced as an output index **SHOULD** be filled in with the 0xFFFFFFFF value. Each entry that is referenced first as an output index and then as input indexes **SHOULD** also be initialized to the 0xFFFFFFFF value.

Multiple ROPs in a buffer can use the same Server Object Handle Table index. For example, a **RopOpenFolder** can specify index 1 as the location to place the handle for the folder Server Object. Later in the same buffer, a **RopGetContentsTable** can specify index 1 as the location for the input Server Object handle.

### 3.1.4.2 Logon

The client specifies the logon ID associated with the logon Server Object created by a **RopLogon** request. The client manages the identifiers in use by use of a Logon Collection. Any 8-bit integer value is allowed for the logon ID and the client does not have to specify logon IDs in a certain numeric order. If the client specifies an active logon ID, the current logon is released and replaced with the new one.

### 3.1.5 Message Processing Events and Sequencing Rules

The client finds the responses for the operations in this output buffer in the same order as sent in the input buffer. The output buffer can also include ROP responses that do not have corresponding ROP requests in the input buffer. These extra ROP responses include **RopBackoff**, **RopBufferTooSmall**, **RopNotify**, and **RopPending**.

#### 3.1.5.1 Extra ROP Responses

##### 3.1.5.1.1 RopBackoff

Any client reporting its version as 12.0.4228.0 or later (as specified in [MS-OXCRPC]) MUST support processing the **RopBackoff** response buffer. The layout of this ROP is specified in section 2.2.14.2.

**RopBackoff** can appear at any location in the ROP output buffer. This ROP response indicates that the server requests the client delay the resending of ROP requests for the specified logon or type of ROPs for an amount of time. When this response contains a non-zero **RopIdBackoff**, it specifies the ROP request that needs to be delayed. The ROP response that was delayed and all subsequent ROP responses will not be in the buffer. When the **RopIdBackoff** is set to 0x00, this indicates that all ROP requests for that logon should be delayed.

##### 3.1.5.1.2 RopBufferTooSmall

The layout of this ROP is specified in section 2.2.14.1.

**RopBufferTooSmall** can appear at any location in the **Rops** field in the ROP buffer. This ROP response indicates that the size of the output buffer is insufficient to return responses for all the ROP requests sent. The **RopBufferTooSmall** includes all the ROP Requests that were not executed by the server. The client SHOULD resend the unexecuted ROP requests in a new call to the server. The client MUST also specify an output buffer size that is at least as large as the size specified in the **RopBufferTooSmall** response.

##### 3.1.5.1.3 RopNotify and RopPending

These ROP responses appear at the end of the ROP output buffer. More detailed information about these ROPs can be found in [MS-OXCNOTIF].

### 3.1.5.2 Server Object Dependencies

The client **MUST** use **RopRelease** to release an object. The client **MUST** release an owned object before releasing the object's owner. For example, a stream object that is owned by a folder is released before the owning folder is released. A summary of object owners and the objects that they can own is provided below.

An attachment owns the following:

- A stream that is opened on properties of the attachment.
- An embedded message that is created from the attachment.
- A fast-transfer source stream that is opened by **RopFastTransferSourceCopyTo** or **RopFastTransferSourceCopyProperties**.
- A fast-transfer destination stream that is opened by **RopFastTransferDestinationCopyTo** or **RopFastTransferDestinationCopyProperties**.

A message owns the following:

- An attachment of the message.
- A stream that is opened on properties of the message.
- An attachments table that is opened on the message.
- A fast-transfer source stream that is opened by **RopFastTransferSourceCopyTo** or **RopFastTransferSourceCopyProperties**.
- A fast-transfer destination stream that is opened by **RopFastTransferDestinationCopyTo** or **RopFastTransferDestinationCopyProperties**.

A folder owns the following:

- A stream that is opened on properties of the folder.
- A rules table that is opened on the folder.
- A permissions table that is opened on the folder.
- A fast-transfer source stream that is opened by **RopFastTransferSourceCopyTo** or **RopFastTransferSourceCopyProperties**.
- A fast-transfer source stream that is opened by **RopSynchronizationConfigure**, **RopFastTransferSourceCopyMessages**, or **RopFastTransferSourceCopyFolder**.
- A fast-transfer destination stream that is opened by **RopFastTransferDestinationCopyTo** or **RopFastTransferDestinationCopyProperties**.

- A fast-transfer destination stream that is opened by **RopFastTransferDestinationCopyMessages** or **RopFastTransferDestinationCopyFolder**.
- A **synchronization upload context** (also called a **collector**) that is opened by **RopSynchronizationOpenCollector**.

### 3.1.6 Timer Events

None.

### 3.1.7 Other Local Events

None.

#### 3.1.7.1 Shutdown

When the client shuts down, it **SHOULD** send **RopRelease** requests to the server to clean up all Server Objects it had created but had not yet released before it disconnects.

## 3.2 *Server Details*

### 3.2.1 Abstract Data Model

This section describes a conceptual model of possible data organization that an implementation maintains to participate in this protocol. The described organization is provided to facilitate the explanation of how the protocol behaves. This document does not mandate that implementations adhere to this model as long as their external behavior is consistent with that specified in this document.

**Logon Map:** A mapping of LogonIds and logon Server Objects.

**Server Object Map:** A mapping of Server Object Handles and Server Objects. There is one map for each logon Server Object.

### 3.2.2 Timers

None.

### 3.2.3 Initialization

When a connection is first set up between a client and server via the EMSMDB interface specified in [MS-OXCRPC], the Server Object Map and Logon Map are empty.

### 3.2.4 Higher-Layer Triggered Events

#### 3.2.4.1 Notifications

More detailed information about notifications can be found in [MS-OXCNOTIF].

### 3.2.4.2 Backoff

When the server determines that a ROP request needs to be delayed, the server **MUST** respond with either a **RopBackoff** response or fail the RPC call.

If the server version is greater than 08.00.0525.0, and the client version is greater than 12.0.4228.0, the server **SHOULD** add a **RopBackoff** response buffer is returned in place of the response for the ROP request. If either the client or the server are earlier versions, the server **MUST** instead fail the RPC call by raising the `RPC_S_SERVER_TOO_BUSY` exception as specified in [MS-OXCRPC].

If ROPs are specified in a **RopBackoff** response, then all subsequent ROP requests **SHOULD NOT** be processed.

### 3.2.4.3 Insufficient Output Buffer Space

When the server determines that there is not enough space remaining in the output ROP buffer for responses for remaining ROPs, it **MUST NOT** execute the remaining ROPs. If the client is able to resubmit the remaining ROPs in another call, then the server **MUST** use a **RopBufferTooSmall** response. If another call would fail, such as if one ROP response is larger than the maximum output `RopBufferSize`, the server **MUST** fail the RPC call returning `0x0000047D`.

## 3.2.5 Message Processing Events and Sequencing Rules

### 3.2.5.1 Processing an Input ROP Buffer

When processing an input ROP buffer received from a client, the server **MUST** execute the ROP requests in the order they are specified in the ROP buffer and **MUST NOT** process more than one input ROP buffer concurrently for a connection. The ROP responses in the output ROP buffer **MUST** also be in the same order in which they were executed.

If the server is unable to parse the ROP requests in the input ROP buffer, the RPC call **MUST** fail by returning `0x000004B6`.

During execution of a ROP request, the server needs to resolve the Server Object Handle Table index to a Server Object. Any index used for input is converted into the corresponding Server Object by looking up the handle in the Server Object Handle Table and then looking up the Server Object Handle in the Server Object Map associated with the logon for the ROP request. If any lookup in the Logon Map or the Server Object Map fails, the server **MUST** fill in a failure ROP response with a non-zero return value.

After successful execution of a ROP request that created a Server Object, the server **MUST** assign an unused Server Object Handle to the object and record the mapping in the Server Object Map for the logon associated with the Rop. The handle assigned is then set in the Server Object Handle Table at the location specified by the output index in the ROP request and can be potentially used by subsequent ROP requests in the buffer.

Because the Server Object Handle value 0xFFFFFFFF is used to initialize unused entries of a Server Object Handle Table, a server MUST NOT assign that value to a created Server Object.

### 3.2.5.2 Creating an Output ROP Buffer

After processing the input ROP buffer, a list of ROP responses and a modified Server Object Handle Table are specified in the output ROP buffer created by the server. This table MUST be large enough to contain an entry for the highest Server Object Handle Table index specified in the ROP responses. The table can be a smaller size compared to the table in the input ROP buffer if entries at the end of the table were not referenced. The server MUST preserve the order of entries in the Server Object Handle Table between the input and output tables.

### 3.2.5.3 RopRelease

The format for the **RopRelease** request buffer is specified in section 2.2.14.3.

This request is used when the client is done with a Server Object. The server MUST remove the mapping for the Server Object Handle from the Server Object Map and release the resources associated with it. The same Server Object Handle can now be reused for another Server Object. If the Server Object specified is a logon Server Object, then the server MUST also remove it from the Logon Map.

Unlike all other ROP requests, **RopRelease** does not have any associated ROP response. The server MUST not return any response for a **RopRelease** request. Any errors resulting from the execution of this ROP MUST be ignored and not sent back to the client.

### 3.2.6 Timer Events

None.

### 3.2.7 Other Local Events

#### 3.2.7.1 Disconnection

When the client disconnects, the server MUST release all Server Objects, Logon Maps, and Server Object Maps associated with the connection.

### 4.5.3 Description

This buffer shows a **RopOpenMessage** call that would produce a response that wouldn't fit in the buffer (the output buffer was much smaller than usual for this example). The

**RopBufferTooSmall** indicates that it would need at least 0x002C bytes to return a response buffer. The **RopOpenMessage** request and the Server Object Handle Table are the same as what would have been specified in the input ROP buffer. In this buffer, the **RopBufferTooSmall** is the first ROP, which indicates that no ROPs were executed before running out of room.
