# [MS-OXOABKT]: Address Book User Interface Templates Protocol Specification

#### **Intellectual Property Rights Notice for Open Specifications Documentation**

- Technical Documentation. Microsoft publishes Open Specifications documentation for protocols, file
  formats, languages, standards as well as overviews of the interaction among each of these
  technologies.
- Copyrights. This documentation is covered by Microsoft copyrights. Regardless of any other terms that are contained in the terms of use for the Microsoft website that hosts this documentation, you may make copies of it in order to develop implementations of the technologies described in the Open Specifications and may distribute portions of it in your implementations using these technologies or your documentation as necessary to properly document the implementation. You may also distribute in your implementation, with or without modification, any schema, IDL's, or code samples that are included in the documentation. This permission also applies to any documents that are referenced in the Open Specifications.
- No Trade Secrets. Microsoft does not claim any trade secret rights in this documentation.
- Patents. Microsoft has patents that may cover your implementations of the technologies described in the Open Specifications. Neither this notice nor Microsoft's delivery of the documentation grants any licenses under those or any other Microsoft patents. However, a given Open Specification may be covered by Microsoft's Open Specification Promise (available here: <a href="http://www.microsoft.com/interop/osp">http://www.microsoft.com/interop/osp</a>) or the Community Promise (available here: <a href="http://www.microsoft.com/interop/cp/default.mspx">http://www.microsoft.com/interop/cp/default.mspx</a>). If you would prefer a written license, or if the technologies described in the Open Specifications are not covered by the Open Specifications Promise or Community Promise, as applicable, patent licenses are available by contacting iplg@microsoft.com.
- Trademarks. The names of companies and products contained in this documentation may be covered
  by trademarks or similar intellectual property rights. This notice does not grant any licenses under
  those rights.
- Reservation of Rights. All other rights are reserved, and this notice does not grant any rights other than specifically described above, whether by implication, estoppel, or otherwise.
- Tools. The Open Specifications do not require the use of Microsoft programming tools or
  programming environments in order for you to develop an implementation. If you have access to
  Microsoft programming tools and environments you are free to take advantage of them. Certain Open
  Specifications are intended for use in conjunction with publicly available standard specifications and

network programming art, and assumes that the reader either is familiar with the aforementioned material or has immediate access to it.

# 1 Introduction

The Address Book User Interface Templates protocol is an extension of the Name Service Provider Interface (NSPI) protocol, as specified in [MS-NSPI]. The Address Book User Interface Templates protocol specifies the following:

- A server-provided **template** for creating specific, single-use e-mail addresses.
- A server-provided layout specification that the client can use for displaying Address
   Book object information.

# 1.1 Glossary

The following terms are defined in [MS-OXGLOS]:

address book **Address Book object Address Creation table** address creation template **Augmented Backus-Naur Form (ABNF) button control** code page display template distinguished name (DN) double-byte character set (DBCS) mail user non-Unicode **Name Service Provider Interface (NSPI) Permanent Entry ID** property remote procedure call (RPC) Simple Mail Transfer Protocol (SMTP) template

The following data types are defined in [MS-DTYP]:

Boolean BYTE ULONG

The following terms are specific to this document:

**check box control**: A **dialog control** that displays a static string and a box that can be

checked and unchecked to indicate that an option is selected.

creation template: See Address Creation template.

**dialog control**: A graphical user interface element that allows a client to interact with a user by displaying information to the user and getting input from the user.

**drop-down list box control**: A **dialog control** that contains a list of possible options of which only the currently selected one is shown. A button on the end of the control can be clicked to display the entire list of available options.

edit control: A dialog control that displays an editable string to the user.

**group box control**: A **dialog control** that contains other **dialog controls** and around which a box is shown with a static string that labels the box.

**label control**: A **dialog control** that displays a static string to the user.

**list box control**: A **dialog control** that contains a list of possible options of which one can be selected by the user.

**page control**: A **dialog control** that contains other controls, groups them together, and displays a static string that describes them at a tab at the top of the group. These controls can be placed on top of each other and the control for which the tab is selected has its set of controls shown.

**search template**: A **template** that describes a dialog for the user to specify criteria for searching **Address Book objects** that meet the criteria.

MAY, SHOULD, MUST, SHOULD NOT, MUST NOT: These terms (in all caps) are used as described in [RFC2119]. All statements of optional behavior use either MAY, SHOULD, or SHOULD NOT.

#### 1.2.2 Informative References

None.

#### 1.3 Protocol Overview

The Address Book User Interface Templates protocol is used for the following three purposes:

- Creation of new e-mail addresses for supported e-mail address types.
- Display and updating of data for different Address Book objects.
- Collection of data to perform searches on an address book.

#### 1.3.1 Creation of New E-Mail Addresses

The creation of new e-mail addresses for supported e-mail address types is the first purpose of the Address Book User Interface Template protocol. By far the most common e-mail address type is the **Simple Mail Transfer Protocol (SMTP)** address type, but the server can support a number of different e-mail address types. This protocol provides a way for **address book** servers to expose the supported address book types to clients and provide a way for the client to create one of these addresses.

The creation of a new e-mail address is a two-step process. First, the client retrieves from the server a list of available address types and the name of the corresponding **creation template** that will be used to create an address of that type. The client can use this list to allow the user to select which address type to create. In the second step, the client requests the creation template that is associated with the selected address type, and uses the **template** to display a dialog to the user and get the necessary information to create the address by using the script that is returned with the template.

#### 1.3.2 Display and Updating of Data

The second purpose of the Address Book User Interface Templates protocol is to display and update data for **Address Book objects**. For the purposes of this protocol, the server acts mainly as a database that stores user interface **templates** and then returns them to the client when requested. The client can then use the templates to display and edit data for Address Book objects.

To display and edit data about a particular Address Book object, the client requests a **display template** from the server and uses the returned template along with data that it has retrieved from the Address Book object [MS-OXOABK] to display a dialog to the user. The client can allow the user to change this data and then update the Address Book object to reflect the user's changes.

#### 1.3.3 Collection of Search Data

The third purpose of the Address Book User Interface Templates protocol is to collect data that will be used to search the **address book**. For the purposes of this protocol, the server acts mainly as a database that stores user interface **templates** and simply returns them to the client when requested. The client can then use the templates to display a dialog to the user to collect data that it needs to perform search operations on the address book.

To collect data to perform search operations on the address book, the client requests a **search template** from the server and uses the returned search template to display a dialog and collect data to create a filter for the address book to locate **Address Book objects**.

# 1.4 Relationship to Other Protocols

The Address Book User Interface Templates protocol specification relies on an understanding of how to work with **Address Book objects**, **properties**, and tables (for more details, see [MS-OXOABK]). The specification also relies on an understanding of how the Address Book Object protocol is used to communicate with the server by using the underlying **RPC** transport.

# 1.5 Prerequisites/Preconditions

The Address Book User Interface Templates protocol assumes that the underlying Address Book Object protocol transport has been properly initialized.

# 1.6 Applicability Statement

The Address Book User Interface Templates protocol can be used to assist a user agent with creating e-mail addresses for supported address types and for displaying, creating, or modifying data associated with an **Address Book object**.

# 1.7 Versioning and Capability Negotiation

None.

Release: Friday, April 10, 2009

## 1.8 Vendor-Extensible Fields

None.

# 1.9 Standards Assignments

None.

# 2 Messages

# 2.1 Transport

This protocol uses the Name Service Provider Interface (NSPI) protocol as a transport for communicating between client and server. In particular, the client will use the two **RPC** functions **NspiGetSpecialTable** and **NspiGetTemplateInfo**, as specified in sections 3.1.4.3 and 3.1.4.20 of [MS-NSPI], to retrieve data from the server.

# 2.2 Message Syntax

The following sections specify the format of data that are specific to the Address Book User Interface Templates protocol that are returned from the **NspiGetSpecialTable** and **NspiGetTemplateInfo** function calls.

# 2.2.1 NspiGetSpecialTable PropertyRowSet r format

The *dwFlags* parameter that is passed to **NspiGetSpecialTablefunction**, as specified in the Name Service Provider Interface protocol, affects the data that is returned in the *PropertyRowSet\_r* output parameter. The bit flag values for the *dwFlags* parameter for this function are documented in the Name Service Provider Interface protocol specification [MS-NSPI]. The client MUST pass the AB\_ONE\_OFF flag to retrieve the table of supported address types from the server and MUST NOT pass any of the other flags. The **properties** listed in the following table MUST be returned by the server in the **PropertyRow\_r** structure that is contained in the *PropertyRowSet\_r* return parameter of the call.

Property	Description	
PidTagAddressType	String property that indicates the type of	
	address that is associated with the new	
	recipient created with the <b>template</b> .	
PidTagDisplayName	String property that contains a user-	
	readable identification of the address type.	
PidTagDisplayType	A LONG property contains a constant that	
	identifies the type of Address Book object	
	that the new recipient will be and therefore	
	what icon the client will display for it. See	

	[MS-OXOABK] for values.		
PidTagEntryId	Binary property that contains the <b>entry ID</b>		
	of the <b>template</b> to be used to create the		
	new recipient. This identifier can be parsed		
	to get the <b>DN</b> to be passed to		
	NspiGetTemplateInfo to retrieve the		
	template. See [MS-NSPI] for the format of		
	Permanent Entry IDs.		
PidTagDepth	<b>LONG</b> property that MUST be ignored.		
<b>PidTagSelectable</b>	<b>Boolean</b> property that MUST be ignored.		
PidTagInstanceKey	Binary property that contains a unique		
	binary value.		

# 2.2.2 NspiGetTemplateInfo PropertyRow r format

The *dwFlags* parameter, which is passed to the **NspiGetTemplateInfo** function, as specified in [MS-OXOAB], affect what properties are returned in the *PropertyRow\_r* return parameter. The flags for this function are specified in [MS-NSPI].

The following table lists the flags that are used by this protocol that can be passed in the *dwFlags* parameter of **NspiGetTemplateInfo** and the corresponding properties that are returned in the **PropertyRow** r return parameter.

Flag	Property Added to PropertyRow_r	Description of contents of property	
TI_TEMPLATE 0x00000001	PidTagTemplateData 0x00010102	Binary <b>property</b> that contains a <b>TRowSet</b> structure followed by data that is pointed to in the <b>TRowSet</b> structure (the format specified in section 2.2.2.1).	
TI_SCRIPT 0x00000004	PidTagScriptData 0x00040102	Binary property that contains script instructions and data (the format specified in section 2.2.2.2).	

#### 2.2.2.1 Template Format

The dialog **template** consists of a set of rows that are represented by a **TRowSet** structure (see section 2.2.2.1.1) with each **TRow** structure describing one control in the dialog. To create the dialog from the template, each control that is described in a **TRow** structure MUST be added to a dialog in the location and and with the size specified.

The **control flags** field, as specified in section 2.2.2.1.2, indicates additional information about the control, including whether it is editable. The control structure will indicate which static strings are to be used for the control, and the **property** that can be used to initialize the control and can be updated if the user edits the value in the control. When a **page control** is encountered, a new tabbed page is added to the dialog, and the controls that follow the page control are placed on that page.

#### 2.2.2.1.1 TRowSet Structure

A **TRowSet** structure is defined in the following table.

Name	Туре	Size in Bytes	Description
Туре	ULONG	4	Type of the template. This MUST be 0x00000001.
cRows	ULONG	4	Count of <b>TRows</b> that are defined in this structure. This field MUST be followed by exactly <i>cRows</i> <b>TRow</b> structures.
Row1	TRow structure	36	TRow structure that contains data about a control.
Row2	TRow structure	36	TRow structure that contains data about a control.
RowN	TRow structure	36	Last of <i>cRows</i> <b>TRow</b> structures.

#### 2.2.2.1.2 TRow Structure

Each **TRow** structure describes a control that MUST be presented to the user in a **display area**. The display area is measured in pixels.

A **TRow** structure is defined in the following table.

Release: Friday, April 10, 2009

Name	Type	Size in Bytes	Description
XPos	ULONG	4	X coordinate of the upper-left corner of the control. For more details, see the following text.
DeltaX	ULONG	4	Width of the control. For more details, see the following text.
YPos	ULONG	4	Y coordinate of the upper- left corner of the control. For more details, see the following text.
DeltaY	ULONG	4	Height of the control. For more details, see the following text.
ControlType	ULONG	4	Type of the control. For more details, see the following text.
ControlFlags	ULONG	4	Flags that describe the control's attributes. For more details, see the following text.
ControlStructure	CNTRL structure	12	Structure that contains data that is relevant to a particular control type.  For more details, see section 2.2.2.1.3.

**XPos** and **YPos** specify the X and Y coordinates of the upper-left corner of the control in pixels in the display area.

**DeltaX** and **DeltaY** specify the width and height of the control in pixels. The values are relative to the **XPos** and **YPos** of the control.

The other three properties describe various characteristics of the control.

**ControlType** indicates the type of control. **ControlType** MUST be one of the values listed in the following table.

Value	Description	
0x00000000	A label control.	
0x00000001	An edit text box control.	
0x00000002	A list box control.	
0x00000005	A check box control.	
0x00000006	A group box control.	
0x00000007	A button control.	
0x00000008	A tabbed page control.	
0x0000000B	A multi-valued list box control that is populated by a multi-valued <b>property</b> .	
0x000000C	A multi-valued <b>drop-down list box control</b> that is populated by a multi-valued property of type string.	

**ControlFlags** is a bit field that describes the attributes of the control and MUST contain any combination of the bits that are specified in the following table for all values of **ControlType**, except for 0x00000008 (tabbed page control), as specified in the Description column. If the value of **ControlType** is 0x00000008, then the value of **ControlFlags** can be any value and MUST be ignored.

Value	Description	
0x0000001	This flag indicates that the control can contain multiple lines. This means that a 0x0D and 0x0A can be entered within the control. This flag SHOULD NOT be set if the value of the <b>ControlType</b> field is any other value except 0x00000001 ( <b>edit box control</b> ). If it is set and the value of <b>ControlType</b> is not 0x00000001, then this flag MUST be ignored.	
0x0000002	This flag indicates that the control can be edited, and the value that is associated with the control can be changed. When this flag is not set, the control is read-only. This value is ignored on the label, group box, button, multi-valued drop-down list box, and list box controls.	
0x0000004	This flag indicates that if the control allows changes (0x00000002 attribute set), then it MUST have a value before the dialog can be dismissed.	
0x00000008	This flag enables immediate setting of a value. As soon as a value in the control changes, that data MUST be updated in the property that is associated with that control.	
0x0000010	This flag indicates the control is treated like a password entry control. The value MUST NOT be displayed by using the actual characters entered. This flag MUST only be set if the value of the <b>ControlType</b> field is 0x00000001 (edit box control).	
0x0000020	If this flag is set, then the <b>edit control</b> MUST allow <b>double-byte character set (DBCS)</b> characters. This flag MUST NOT be set if the value of the <b>ControlType</b> field is any anything except 0x00000001 (edit box control).	
0x0000040	This flag indicates that when a selection is made within the list box, the index column of that list box is set as a property. This flag MUST only be set if the 0x00000008 <b>ControlFlag</b> is also set.	

**ControlStructure** is a **CNTRL** structure that contains information that is relevant to the particular type of control (see section 2.2.2.1.3).

## 2.2.2.1.3 Buffer Format of the CNTRL Structure

The base **CNTRL** structure is as follows, with each entry taking a different meaning, depending on the type of control, as shown in the following table.

Name	Туре	Size	Description	
dwType	DWORD	4	Varies depending on the control. See the following subsections for details.	
ulSize	ULONG	4	Varies depending on the control. See the following subsections for details.	
ulString	ULONG	4	The offset in <b>BYTES</b> from the base of the <b>TRowSet</b> structure to a null-terminated <b>non-Unicode</b> string. This string MUST be in the <b>code page</b> indicated by <i>ulTemplateCodePage</i> parameter of the <b>NspiGetTemplateInfo</b> call and MUST be terminated by a NULL character. In these strings, the "&" (ampersand) has special meaning and indicates that the character that immediately follows it MUST be used as an easy way to select this control. If the control cannot be selected, then the control that follows it is selected. If an "&" needs to be in the string and it SHOULD NOT have any special meaning, then a sequence of "&&" can be used to indicate this.  For more details about string values, usage, and limitatitons, see the following subsections.	

# 2.2.2.1.3.1 CNTRL Structure Describing a Label Control

dwType - MUST be 0x00000000 and MUST be ignored.

ulSize - SHOULD be 0x00000000 and MUST be ignored.

**ulString** - String that contains label text of **label control**. The string MUST NOT be over 128 characters long, including the NULL-terminating character.

# 2.2.2.1.3.2 CNTRL Structure Describing a Edit Control

Release: Friday, April 10, 2009

**dwType** – **Property** of data entered into the edit box control.

**ulSize** – Number of characters allowed to be entered into the edit box control.

**ulString** – String that contains a regular expression that describes the allowed characters that can be entered into the **edit control** (see the following subsection). The string MUST NOT be over 15 characters long, including the NULL-terminating character.

# 2.2.2.1.3.2.1 Expression Syntax for Allowed Characters

The filter string has two possible expressions. The first expression allows any character to be entered into the **edit control**, and this expression is simply a string that contains only the "\*" (asterisk) character. The second expression lists the characters that are valid to be entered or that are invalid to be entered into the edit control. This expression is shown in **ABNF** [RFC4234] in the following format:

"[" \*1("~") 1\*(char-val / char-val "-" char-val ) "]"

The expression MUST be included in square brackets ("[]"). When the first character inside the brackets is the tilde ("~") character, the expression represents characters that are not allowed in the edit control; otherwise, it represents only the characters that are allowed in the edit control. The rest of the characters inside the brackets are characters or ranges of characters to be allowed or disallowed from the edit control.

To represent any character that is a special character in this expression syntax with a backslash character ("\"), the backslash character can be placed in front of the character. The backslash character will be ignored, and the character that follows it will be treated as a normal character and not as a special character. To represent a single character to allow/disallow, the character (with the leading backslash if necessary) is put in the string. To represent a range of characters to allow/disallow, the first character in the range is put in the string, followed by a dash ("-") character, followed by the final character in the range. The combination of all individual characters and character ranges is the set of characters that will be allowed or disallowed.

For example, if only the characters A, F, and T through Z are allowed to be entered into the control, then the expression is:

[AFT-Z]

If you want to allow all characters except the"[" (which will need the backslash character) and Z characters, then the expression is:

 $[\sim \setminus [Z]$ 

#### 2.2.2.1.3.3 CNTRL Structure Describing a List Box Control

**dwType** – **Property** of the table to populate this **list box control** from and to which the data from this list box control SHOULD be saved.

ulSize – SHOULD be 0x00000000 and MUST be ignored.

**ulString** –MUST be a string that contains only the character "\*"and MUST be ignored.

16 of 64

# 2.2.2.1.3.4 CNTRL Structure Describing a Check Box Control

**dwType** – **Property** of data that is represented by this **check box control**.

ulSize – SHOULD be 0x00000000 and MUST be ignored.

**ulString** – String that contains the label text of check box control. The string MUST NOT be over 128 bytes long, including the NULL terminating character.

## 2.2.2.1.3.5 CNTRL Structure Describing a Group Box Control

**dwType** – SHOULD be 0x00000000 and MUST be ignored.

ulSize – SHOULD be 0x00000000 and MUST be ignored.

**ulString** – String that contains the label text of the **group box control**. The string MUST NOT be over 128 bytes long, including the NULL-terminating character.

## 2.2.2.1.3.6 CNTRL Structure Describing a Button Control

**dwType** – **Property** that is used to perform an action. This value MUST be **PidTagAddressBookManageDistributionList** (see [MS-OXOABK]). If this value is anything else, it MUST be ignored.

ulSize – MUST be 0x00000000 and MUST be ignored.

**ulString** – String that contains the label text of the **button control**. The string MUST NOT be greater than 128 bytes in length, including the NULL-terminating character.

# 2.2.2.1.3.7 CNTRL Structure Describing a Tabbed Page Control

**dwType** – SHOULD be 0x00000000 and all other values MUST be ignored.

ulSize – SHOULD be 0x00000000 and MUST be ignored.

**ulString** – String that contains the label text of the tabbed **page control**. The string MUST NOT be greater than 32 bytes in length, including the NULL-terminating character.

## 2.2.2.1.3.8 CNTRL Structure Describing a Multi-Valued List Box Control

**dwType** – **Property** for multi-valued data that is displayed in this **list box control**.

ulSize –SHOULD be 0x00000000 and MUST be ignored.

ulString –MUST be a string that contains only the character "\*"and MUST be ignored.

# 2.2.2.1.3.9 CNTRL Structure Describing a Multi-Valued Drop-Down List Box Control

**dwType** – **Property** for the multi-valued data that is displayed in this **list box control**.

ulSize – SHOULD be 0x00000000 and MUST be ignored.

ulString – MUST be a string that contains only the character "\*" and MUST be ignored.

# 2.2.2.2 Script Format

A script is a set of instructions that are processed by using data collected by the **template** to produce a new e-mail address. The **PidTagScriptData property** in the PropertyRow\_r is a binary property that contains the information listed in the following table.

Name	Туре	Size	Description
Size	DWORD	4	Specifies the number of <b>DWORDs</b> of script data that follow.
ScriptData	DWORD Array	Varies	Specifies a series of instructions and the data that accompanies them, as specified in the following subsections.

This binary script data contains a series of instructions (as specified in the following subsections) that can be executed to format an address and the data that is needed to execute those instructions. The first **DWORD** contains the number of **DWORDs** of instructions, "N". The next *N* **DWORDs** are the instructions. The data that is referenced by the instructions immediately follows the instructions.

The script is used to create a string that contains the e-mail address from the data gathered from the dialog that was created from the **template**. To process the script, begin at the first **DWORD** of *ScriptData* and process each instruction in turn. The result of the script is the result string. The result string MUST initially be empty and various instructions will append data to it. This string is the object's e-mail address and MUST only be used if the script doesn't end in error.

The instructions are specified in the following sections.

#### **2.2.2.2.1.1** Halt Instruction

Halt instruction is one **DWORD**, as shown in the following table.

Name	Туре	Size	Value
Halt	DWORD	4	0x00000000

When this instruction is encountered, the script has finished and was successful. Processing MUST be halted and the current value of the result string is the e-mail address.

#### 2.2.2.2.1.2 Error Instruction

Error instruction is one **DWORD**, as shown in the following table.

Name	Туре	Size	Value
Error	DWORD	4	0x0000001

When this instruction is encountered, the script is over and has ended in an error. Processing MUST be halted and the result string MUST NOT be used.

#### 2.2.2.2.1.3 Emit String Instruction

Emit String instruction is a 2-DWORD instruction and is as shown in the following table.

Name	Туре	Size	Value
Emit String	DWORD	4	0x80000002
First Operand	DWORD	4	See the following text.

The *First Operand* is an offset in **BYTEs** from the start of the *ScriptData* in the **PidTagScriptData property's** binary data to a **non-Unicode** null-terminated string, which is used as the operand for this instruction. When this instruction is encountered, the script MUST append the operand string to the result string and advance to the next instruction.

## 2.2.2.2.1.4 Jump Instruction

Jump instruction is a 2-**DWORD** instruction, as shown in the following table.

Name	Туре	Size	Value
Jump	DWORD	4	0x00000003
Jump Offset	DWORD	4	See the following text.

The *Jump Offset* parameter is an offset in **BYTEs** from the start of the *ScriptData* in the **PidTagScriptData property's** binary data where the next instruction to execute is located.

When this instruction is encountered, the script MUST continue its execution from the instruction at the offset indicated.

## 2.2.2.2.1.5 **Jump If Not Exists Instruction**

Jump If Not Exists instruction is a 3-DWORD instruction, as shown in the following table.

Name	Туре	Size	Value
Jump If Not Exists	DWORD	4	0x00000004
First Operand	DWORD	4	See the following text.
Jump Offset	DWORD	4	See the following text.

The *First Operand* is a parameter that indicates a property that SHOULD be retrieved from the data collected by using the **template**.

The *Jump Offset* is an offset in **BYTEs** from the start of the *ScriptData* in the **PidTagScriptData** property's binary data where the next instruction to execute is located.

When this operation is encountered, an attempt MUST be made to retrieve the property from the data collected by using the template. If the property was successfully retrieved, then the script is advanced over this instruction and execution continues. If the property fails to be retrieved, then the script will continue execution from the instruction at the offset indicated in *Jump Offset*.

## **2.2.2.2.1.6 Jump If Equal Properties Instruction**

Jump If Equal Properties instruction is a 4-**DWORD** instruction, as shown in the following table

Name	Туре	Size	Value
Jump If Equal Properties	DWORD	4	0x00000005
First Operand	DWORD	4	See the following text.
SecondOperand	DWORD	4	See the following text.
Jump Offset	DWORD	4	See the following text.

The *First Operand* is a parameter that indicates a **property** that will be retrieved from the data collected by using the **template**. The value of the property MUST be either a **non-Unicode** 

null-terminated string or a **Boolean**. The value retrieved from the data collected by using the **template** is used as the first operand for the instruction.

The *Second Operand* is a parameter that indicates a property that will be retrieved from the data collected by using the template. The value of the property MUST be either a **non-Unicode** string or a Boolean and its type MUST match that of the *First Operand*. This value retrieved from the data that is collected by the template is used as the second operand for the instruction.

The *Jump Offset* is an offset in **BYTEs** from the start of the *ScriptData* in the **PidTagScriptData** property's binary data where the next instruction to execute is located.

When this operation is encountered, the first two operands are compared, and if they are not equal, the script is advanced over this instruction and execution continues. If they are equal, the script will continue execution with the instruction at the offset indicated in the *Jump Offset*.

# 2.2.2.2.1.7 Jump If Equal Values Instruction

Jump If Equal Values instruction is a 4-**DWORD** instruction and is shown in the following table.

Name	Туре	Size	Value
Jump If Equal Values	DWORD	4	0x40000005
First Operand	DWORD	4	See the following text.
Second Operand	DWORD	4	See the following text.
Jump Offset	DWORD	4	See the following text.

The *First Operand* is a parameter that indicates a **property** that will be retrieved from the data collected by using the **template**. The value of the property MUST be either a **non-Unicode** string or a **Boolean**. The value retrieved from the object is used as the first operand for the instruction.

The *Second Operand* is an offset in bytes from the start of the *ScriptData* in the **PidTagScriptData** property's binary data where data is located, which is used as the second operand for this instruction. The type of the second operand is determined by the type of the first operand. Specifically, if the first operand is a Boolean, then the second operand is also treated as a Boolean, and if the first operand is a non-Unicode null-terminated string, then the second operand is also treated as a non-Unicode null-terminated string.

The *Jump Offset* is an offset in bytes from the start of the *ScriptData* in the **PidTagScriptData** property's binary data where the next instruction to execute is located.

When this operation is encountered, the values of the first two operands are compared, and if they are not equal, the script is advanced over this instruction and execution continues. If they are equal, the script will continue its execution with the instruction at the offset indicated in the *Jump Offset*.

# 2.2.2.2.1.8 Emit Property Value Instruction

Emit Property value instruction is a 2-DWORD instruction, as shown in the following table.

Name	Туре	Size	Value
Emit Property Value	DWORD	4	0x00000002
First Operand	DWORD	4	See the following text.

The *First Operand* is a parameter that MUST be retrieved from the data collected by using the **template**. The value of the **property** MUST be a **non-Unicode** string and MUST be terminated by a NULL character. The value will be used as the operand for this instruction. When this instruction is encountered, the script MUST append the operand string to the result string and advance to the next instruction.

### 2.2.2.2.1.9 Emit Upper String Instruction

Emit Upper String instruction is a 2-DWORD instruction, as shown in the following table.

Name	Туре	Size	Value
Emit Upper String	DWORD	4	0x80000006
First Operand	DWORD	4	See the following text.

The *First Operand* is an offset in **BYTEs** from the start of the *ScriptData* in the **PidTagScriptData property's** binary data to a **non-Unicode** null-terminated string, which is used as the operand for this instruction. When this instruction is encountered, the script MUST first convert the operand string to all uppercase letters and then append the string to the script's result string and advance to the next instruction.

#### 2.2.2.2.1.10 Emit Upper Property Instruction

Emit Upper Property instruction is a 2-DWORD instruction, as shown in the following table.

Name	Туре	Size	Value
Emit Upper Property	DWORD	4	0x00000006

Name	Туре	Size	Value
First Operand	DWORD	4	Property of property to fetch and use as an operand.

The *First Operand* is a parameter that will be retrieved from the data collected by using the **template**. The value of the property MUST be a **non-Unicode** null-terminated string, and it is used as the operand for this instruction. When this instruction is encountered, the script MUST first convert the operand string to all uppercase letters, and then append the string to the script's result string and advance to the next instruction.

# 3 Protocol Details

# 3.1 Client Details

#### 3.1.1 Abstract Data Model

This section describes a conceptual model of possible data organization that a client implementation maintains to participate in this protocol. The described organization is provided to facilitate the explanation of how the protocol behaves. This document does not mandate that implementations adhere to this model as long as their external behavior is consistent with that described in this document.

# 3.1.1.1 Dialog Object

A dialog object is an object that can be displayed to the user and onto which control objects can be placed in specified locations in order to display information and allow the user to update that information.

# 3.1.1.2 Control objects

Control objects are user interface objects that can be used to display to and receive information from the user in various forms. There are eight types of control objects. These are described in the following table.

Control Type	Description
Label	Control used to display a string to the user. This control is not editable.
Edit	Control used to display a simple string to the user and to allow that string to be edited.

List Box	Control that contains a list of possible options of which one is selected. The user can change the selection.
Check Box	Control that displays a string that cannot be changed by the user and a box that can be checked and unchecked to indicate whether the option described by the string is selected.
Group Box	Control that contains other controls and around which is shown a box and a string that is the label for this group of controls.
Button	Control that displays a string to the user that performs a specified action when clicked.
Drop-Down List Box	Control similar to the <b>list box control</b> , except that only the currently selected item in the list is displayed to the user, and an arrow that is displayed on the end of the control causes the entire list to be displayed to the user so that a new item can be selected.
Page	Control that contains other controls. This controlgroups the other controls together and displays a string that describes them as a tab on the group. These controls can be placed on top of each other and the group for which the tab is selected determines the set of controls that will be shown.

# 3.1.1.3 Address Creation Template Table

An **Address Creation template** table is a table that contains a row for each supported address type, the address type's name as it will be displayed to the user, and what **creation template** is associated with it. It will also contain data that describes how to display it to the user.

## **3.1.2** Timers

None.

## 3.1.3 Initialization

The underlying Address Book Object protocol MUST be initialized. There is no initialization specific to the Address Book User Interface Templates protocol.

#### 3.1.4 Higher-Layer Triggered Events

#### 3.1.4.1 Creating a new E-Mail Address for a Supported Address Type

When the client needs to use an e-mail address that does not exist on the **address book** server, it can create a new e-mail address for a supported address type and use this address to identify a recipient.

When the client wants to create a new e-mail address, first the **address creation table** MUST be retrieved by calling **NspiGetSpecialTable** with AB\_ONE\_OFF as the *dwFlags* parameter. The function returns a **PropertyRowSet\_r** structure that contains the data needed to create a list of **creation templates** for the supported address types. This list is then used to select an address type, possibly by displaying this list to the user or by selecting a type programatically. When the address type has been selected, the data from the corresponding **PropertyRow\_r** can be used to determine the **distinguished name (DN)** for the creation template that will be used to create the new e-mail address and its address type. **PidTagAddressType** is the **property** in the **PropertyRow\_r** that indicates the e-mail address type. **PidTagEntryId** is the property in the **PropertyRow\_r** that can be parsed to get the DN. The **PidTagEntryId** is a **Permanent Entry ID**, and its format is specified in [MS-NSPI].

Next, the creation dialog **template** that will be used to create a new e-mail address MUST be retrieved by using the **NspiGetTemplateInfo** call, passing in the **DN** value for the **creation template** that you want as the *pDN* parameter and 0x00000000 as the *ulType* parameter. The *dwFlags* parameter contains a bitwise combination that MUST include the bits for TI\_TEMPLATE (0x00000001) set so that the template will be retrieved, and TI\_SCRIPT (0x00000004) set so the script to format the e-mail address is retrieved, and MAY contain the bits for TI\_HELPFILE\_NAME (0x00000020) and TI\_HELPFILE (0x000000040)<1> for a value of 0x00000065.

The function's *dwCodePage* input parameter is the **code page** in which the strings in the template are stored, and in which the *ppData* return parameter is a pointer to a **PropertyRow\_r** that contains the data needed to create and display a dialog to create the new e-mail address. When the dialog is completed and dismissed, the data from the dialog MUST be used to run the script and create the e-mail address for this entry. This e-mail address MUST be used to populate the **PidTagEmailAddress** property and the address type retrieved from the selected **PropertyRow\_r** MUST be used to populate the **PidTagAddressType** property. These two properties comprise the e-mail address that can be used as an e-mail recipient.

## 3.1.4.2 Displaying Information about an Address Book Object

When a client or user agent wants to view or change the information contained in an **address book** entry, the client MUST retrieve the **display template** for the address book entry's display type and display the data to the user. To retrieve the display dialog template that is used to display information about a particular **Address Book object**, **NspiGetTemplateInfo** MUST be called with the *ulType* parameter set to the display type of the object and the *pDN* 

parameter set to 0x000000000. The *dwFlags* parameter contains a bitwise combination that MUST include the bit for TI\_TEMPLATE (0x00000001) set so the **template** will be retrieved and MAY contain the bits for TI\_HELPFILE\_NAME (0x00000020) and TI\_HELPFILE (0x00000040)<2> for a value of 0x00000061. The function's *dwCodePage* input parameter is the **code page** in which the strings in the template are stored and the *ppData* return parameter contains a pointer to a **PropertyRow\_r** that contains the data needed to create and display the dialog. Data to initialize the dialog MUST be retrieved from the Address Book object by using the properties specified for each control in the dialog in the **PidTagTemplateData property** of the **PropertyRow\_r**, as specified in [MS-NSPI]. If the dialog is updated, then the data from the dialog MUST be used to update the properties that are associated with the controls and these properties MUST be updated on the Address Book object.

## 3.1.4.3 Collecting Data to Search the Address Book

When a client or user agent wants to search the address book for a particular Address Book **object**, the client MUST retrieve the **search template** for the address book and display the template to the user to collect the data to use to search the address book. To retrieve the search template that is used to collect information to use to search the address book. **NspiGetTemplateInfo** MUST be called with the *ulType* parameter set to the DT SEARCH (see definition in [MS-NSPI]) and the pDN parameter set to 0x000000000. The dwFlags parameter contains a bitwise combination that MUST include the bit for TI TEMPLATE (0x00000001) set so the template will be retrieved and MAY contain the bits for TI HELPFILE NAME (0x00000020) and TI HELPFILE (0x00000040)<3> for a value of 0x00000061. The function's dwCodePage input parameter is the code page in which the strings in the template are stored and the ppData return parameter contains a pointer to a **PropertyRow** r that contains the data needed to create and display the dialog. When the dialog is completed and dismissed, the data from the dialog can be used to create a **Restriction** r, as defined in [MS-NSPI], from the controls that have been filled in. This **Restriction** r can be passed to **NspiGetMatches** in the *Filter* input parameter to locate an Address Book object, as specified in [MS-NSPI].

#### 3.1.5 Message Processing Events and Sequencing Rules

The following events MUST be processed by a client that implements the Address Book User Interface Templates protocol. Note that no particular sequence is required for the message processing.

## 3.1.5.1 Results of NspiGetSpecialTable Call to Retrieve the Address Creation Table

The results of the **NspiGetSpecialTable** call when its *dwFlag* parameter is AB\_ONE\_OFF is a **PropertyRowSet\_r** that contains the **address creation table** information (see section 2.2.1). These rows can be displayed as a list to show to users so that they can select the type of address to create. For each row in the **PropertyRowSet\_r**, the **PidTagDisplayName** can be used as the user-visible string in the list. After an address type has been selected, the **PidTagEntryId** in the selected **PropertyRow r** MUST be parsed (for details about the

format, see [MS-NSPI]) and the **distinguished name (DN)** found. This DN value MUST be used as the *pDN* parameter in a call to **NspiGetTemplateInfo** to retrieve the **creation template** and finish the creation of the e-mail address.

# 3.1.5.2 Results of NspiGetTemplateInfo Call to Retrieve the Creation Template

The results of the **NspiGetTemplateInfo** call when the **distinguished name (DN)** for the **creation template** is passed in as the *pDN* parameter of a **PropertyRow\_r** that contains the **template** for the dialog to display and the creation script. The client MUST use the dialog template to create a dialog and display it to the user. The client can create a new Property Bag object that is empty and use it to initialize the dialog so that it is blank. After the user has provided values for all controls that are marked as required, and closes the dialog, the properties that are associated with the controls can be updated in the Property Bag. Then, by using the Property Bag to retrieve these properties when needed, the creation script MUST be executed as specified in section 2.2.2.2 to create the new e-mail address. This e-mail address MUST be used to set the **PidTagEmailAddress property** and the address type from the **address creation table** MUST be used to set the **PidTagAddressType** property to create a new address.

## 3.1.5.3 Results of NspiGetTemplateInfo Call to Retrieve the Display Template

The results of the **NspiGetTemplateInfo** call when the display type of an object is passed in as the *ulType* parameter is a **PropertyRow\_r** that contains the **template** for the dialog to display. The client MUST use the dialog template to create a dialog and display it to the user. The client MUST use the object the type for which was passed in to initialize the dialog. If the user updates any information in the dialog and closes the dialog, the **properties** that are associated with the updated controls MUST be updated in the object.

# 3.1.5.4 Results of NspiGetTemplateInfo Call to Retrieve the Search Template

The results of the **NspiGetTemplateInfo** call when the display type of DT\_SEARCH is passed in as the ulType parameter is a PropertyRow\_r that contains the **search template** for the dialog to display. The client MUST use the search template to create a dialog and display it to the user for input. If the user inputs any information into the dialog and closes the dialog, the properties associated with the controls SHOULD be used to create a Restriction\_r to be used as the Filter input parameter in a call to **NspiGetMatches**. **NspiGetMatches** SHOULD handle filters containing properties in the search template.

#### 3.1.6 Timer Events

None.

#### 3.1.7 Other Local Events

None.

#### 3.2 Server Details

#### 3.2.1 Abstract Data Model

This section describes a conceptual model of possible data organization that a server implementation maintains to participate in this protocol. The described organization is provided to facilitate the explanation of how the protocol behaves. This document does not mandate that implementations adhere to this model, as long as their external behavior is consistent with that described in this document.

# 3.2.1.1 Template Objects

The server keeps a Template object for each display type and for the **creation template** for each supported address type in the **address creation table**. These objects contain the **template**, and if needed, the script that will be returned from **NspiGetTemplateInfo** in the **PropertyRow r**.

# 3.2.1.2 Table of Supported Address Types and Name of Template to Use to Create Them

The server can keep a Table object that contains the list of supported address types, the **creation templates** that are associated withthe address types, and any other data that is needed to construct and return the **PropertyRowSet\_r** when it receives a call from **NspiGetSpecialTable**.

#### **3.2.2** Timers

None

#### 3.2.3 Initialization

None.

#### 3.2.4 Higher-Layer Triggered Events

None.

#### 3.2.5 Message Processing Events and Sequencing Rules

The following events MUST be processed by a server that implements the Address Book User Interface Templates protocol. Note that no particular sequence is required for the message processing.

#### 3.2.5.1 NspiGetSpecialTable Call from Client

The client calls in to the server by using the **NspiGetSpecialTable RPC** function with the AB\_ONE\_OFF flag set in the *dwFlags* parameter to retrieve the table of supported address types. The server's handling of any other flags that can be passed to the **NspiGetSpecialTable** 

Release: Friday, April 10, 2009

function are specified in [MS-NSPI]. The server retrieves the table of support address types and MUST format the table into a **PropertyRow r** before returning this data to the client.

# 3.2.5.2 NspiGetTemplateInfo Call from Client

The client calls in to the server by using the **NspiGetTemplateInfo RPC** function with the *dwFlags* parameter that contains some bitwise combination of the bit flags TI\_TEMPLATE (0x00000001) so the **template** will be retrieved, and TI\_SCRIPT (0x0000004) so the script to format the e-mail address is retrieved (see section 2.2.2). The server MUST use the display type specified in the *ulType* input parameter or the template **DN** specified in the *pDN* pinput parameter to retrieve the Template object. Finally, the server MUST create the *PropertyRow\_r* return parameter by using the Template object and return this data to the client.

#### 3.2.6 Timer Events

None

#### 3.2.7 Other Local Events

None.

# 4 Protocol Examples

Starting with a connection bound to the server, the following sections include sample structures that would be returned by the **NSPI** function call.

# 4.1 Creating a New E-Mail Address for a Supported Address Type

To create a new e-mail address for one of the supported address types, the client has to first request the list of supported address types from the server by calling the **NspiGetSpecialTable RPC** function. The first step is to bind to the server by using the **NspiBind** call to retrieve an RPC context handle for the server.

**NspiGetSpecialTable** is then called, passing a AB ONE OFF flag in the *dwFlags* parameter.

The following are the input parameters for the NspiGetSpecialTable call:

dwFlags: 0x00000002
STAT: hIndex=0x0,
 ContainerID=0xccccccc,
 CurrentRec=0x00000000,
 Delta=0x00000000,
 NumPos=0x00000000,
 TotalRecs=0xccccccc
 CodePage =0x4e4
 TemplateLocale=0x409
 SortLocale=0x409

Release: Friday, April 10, 2009

The call returns a **PropertyRowSet\_r** in the *HierTabrows* return parameter. The following is an example of the *HierTabRows* that can be returned:

```
HierTabRows:
                cRows - 0 \times 000000005
     Row0
           cValues - 0x00000007
           ulAdrEntryPad - not used - 0x00000000
                 Prop0
                      ulPropTag - PidTagDisplayName (0x3001001e)
                      ulReserved - not used - 0x00000000
                      Value - cc:Mail Address
                 Prop1
                      ulPropTag - PidTagAddressType (0x3002001e)
                      ulReserved - not used - 0x00000000
                      Value - CCMAIL
                 Prop2
                      ulPropTag - PidTagDisplayType (0x39000003)
                      ulReserved - not used - 0x00000000
                      Value - 0x00000000
                 Prop3
                      ulPropTag - PidTagDepth (0x30050003)
                      ulReserved - not used - 0x00000000
                      Value - 0x00000000
                 Prop4
                      ulPropTag - PidTagSelectable (0x3609000b)
                      ulReserved - not used - 0x00000000
                      Value - 0x0000001
                 Prop5

```

These rows are then used to create a list of address types, and this list is displayed so that the user can choose which type to create. The "cc:Mail Address" row is selected and examined, and the PidTagAddressType and PidTagEntryId values are extracted. The PidTagEntryId is parsed and the DN is determined to be the following:

This value is passed to **NSPIGetTemplateInfo** as the pDN parameter to retrieve the **creation template**. The following are the input parameters that are passed to **NspiGetTemplateInfo**:

**NspiGetTemplateInfo** will return a **PropertyRow\_r** in the *ppData* output parameter, and this **PropertyRow\_r** will contain the template and script data. **NspiGetTemplateInfo** returns the following:

```

```

This **template** can be processed to create a dialog similar to the one shown in Figure 1.

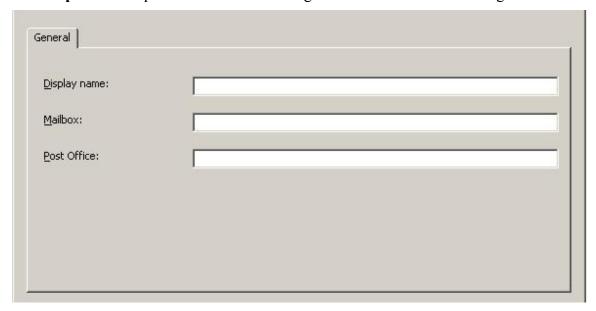

Figure 1: Address creation dialog

The following data is then entered into the dialog:

Display name: Bob

Mailbox: BobsMailbox

Post office: GeneralPostOffice

The script processes the above data, and produces the following e-mail address:

BobsMailbox at GeneralPostOffice

Therefore, the **PidTagEmailAddress** that represents this user is "BobsMailbox at GeneralPostOffice" and the **PidTagAddressType** is "CCMAIL."

### 4.2 Retrieving a Mail User's Template

To display information about an **Address Book object** to the user, the client has to first request the **display template** from the server by calling the **NspiGetTemplateInfo RPC** function. The first step is to bind to the server by using the **NspiBind** call to retrieve an RPC context handle for the server.

For example, **NspiGetTemplateInfo** is called to get the template to display data about a **mail user** by passing *ulType* with the mail user display type (DT MAILUSER).

The following are the input parameters for an example of a call to **NspiGetTemplateInfo**:

```
      dwFlags:
      0x00000061

      dwType:
      0x00000000

      pDN:
      (null)

      ulTemplateCodePage:
      0x000004e4

      ulServerTemplateLocale:
      0x00000409
```

The call returns a **PropertyRow\_r** in the *ppData* return parameter. The following is an example of the *ppData* that can be returned:

```
ppData

By processing the **template** in this **PropertyRow\_r**, the dialog shown in Figure 2 is created.

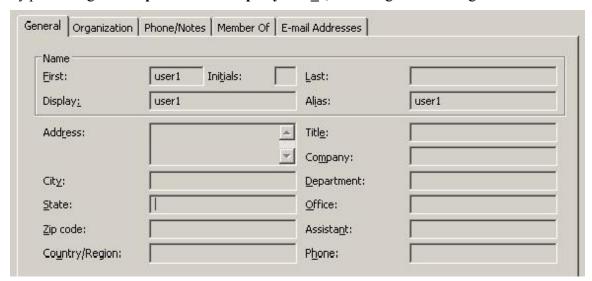

Figure 2: Address Book object display dialog

The client then retrieves the properties specified in the **template** from the requested Address Book object to populate the various **dialog controls**.

## 5 Security

### 5.1 Security Considerations for Implementers

The execution of scripts in this protocol has to be implemented in a secure manner. The script execution checks for valid scripts, but it is also important to be aware of the possibility of infinite loops and other potential security considerations.

General security considerations that pertain to the underlying **NSPI RPC**-based transport also apply (see [MS-NSPI]).

#### 5.2 Index of Security Parameters

None.

# 6 Appendix A: Office/Exchange Behavior

The information in this specification is applicable to the following versions of Office/Exchange:

- Microsoft Office Outlook 2003
- Microsoft Exchange Server 2003
- Microsoft Office Outlook 2007
- Microsoft Exchange Server 2007
- Microsoft Outlook 2010
- Microsoft Exchange Server 2010

Exceptions, if any, are noted below. Unless otherwise specified, any statement of optional behavior in this specification prescribed using the terms SHOULD or SHOULD NOT implies Office/Exchange behavior in accordance with the SHOULD or SHOULD NOT prescription. Unless otherwise specified, the term MAY implies Office/Exchange does not follow the prescription.

62 of 64

<sup>&</sup>lt;1> Section 3.1.4.1: Exchange 2003, Exchange 2007, and Exchange 2010 ignore the TI\_HELPFILE\_NAME and TI\_HELPFILE flags and Outlook 2003, Outlook 2007, and Outlook 2010 currently pass these flags but they have no effect on the results of the **NSPIGetTemplateInfo** function.

<sup>&</sup>lt;2> Section 3.1.4.2: Exchange 2003, Exchange 2007, and Exchange 2010 ignore the TI\_HELPFILE\_NAME and TI\_HELPFILE flags and Outlook 2003, Outlook 2007, and Outlook 2010 currently pass these flags but they have no effect on the results of the **NspiGetTemplateInfo** function.

<3> Section 3.1.4.3: Exchange 2003, Exchange 2007, and Exchange 2010 currently ignore the TI\_HELPFILE\_NAME and TI\_HELPFILE flags and Outlook 2003, Outlook 2007, and Outlook 2010 currently pass these flags but they have no effect on the results of the **NSPIGetTemplateInfo** function.
